

IMPACT OF RECENT NEUTRINO DATA ON R-PARITY VIOLATIONAsmaa Abada ¹, Gautam Bhattacharyya ^{a 2}, Marta Losada ³¹ *Laboratoire de Physique Théorique, Université de Paris XI, Bâtiment 210, 91405 Orsay Cedex, France*² *Saha Institute of Nuclear Physics, 1/AF Bidhan Nagar, Kolkata 700064, India*³ *Centro de Investigaciones, Universidad Antonio Nariño, Cll. 58A No. 37-94, Santa Fe de Bogotá, Colombia*

We take both the bilinear and trilinear R-parity violating couplings in supersymmetric models as a source of neutrino masses and mixings. Using the solar and atmospheric data and the Chooz constraint we determine the allowed ranges of those couplings. We also estimate the effective mass for neutrinoless double beta decay in this scenario.

1 R-parity violation and its parametrization

In supersymmetric models, lepton and baryon numbers (L and B , respectively) are not automatically conserved, unlike in the standard model. In terms of L and B , one defines R-parity as $R_p = (-1)^{3B+L+2S}$, where S is the spin of a particle. Stringent phenomenological limits on R-parity violating (R_p) interactions^{1,2} can be found in Ref. ³. B violation has got nothing to do with neutrino mass generation, and we assume that such interactions are absent. Neutrino Majorana mass generation requires two units of L violation. For this purpose, we allow both bilinear (μ_i) and trilinear (λ, λ') interactions in the superpotential as well as the bilinear soft terms (B_i), given by,

$$W = \mu^J H_u L_J + \frac{1}{2} \lambda^{JK\ell} L_J L_K E_\ell^c + \lambda'^{Jpq} L_J Q_p D_q^c + h_u^{pq} H_u Q_p U_q^c, \quad (1)$$

where the vector $L_J = (H_d, L_i)$ with $J : 4..1$. The soft supersymmetry-breaking potential is

$$V_{soft} = \frac{\tilde{m}_u^2}{2} H_u^\dagger H_u + \frac{1}{2} L^{J\dagger} [\tilde{m}_L^2]_{JK} L^K + B^J H_u L_J \\ + A^{ups} H_u Q_p U_s^c + A^{Jps} L_J Q_p D_s^c + \frac{1}{2} A^{JKl} L_J L_K E_l^c + \text{h.c.} \quad (2)$$

It should be noted that field redefinitions of the H_d, L_i fields correspond to basis changes in L_J space and consequently the Lagrangian parameters will be altered. Hence we use the

basis-independent parameters constructed in^{4,5} and write the neutrino mass matrix in terms of such parameters $\delta_\mu^i, \delta_B^i, \delta_\lambda^{ijk}, \delta_{\lambda'}^{ipq}$, which in the basis in which the sneutrino vacuum expectation values are zero correspond to the Lagrangian parameters $\mu^i/|\mu|, B^i/|B|, \lambda_{ijk}, \lambda'_{ipq}$, respectively.

This talk is mainly based on the paper⁶. For previous studies of $\mathcal{R}_p$ effects on neutrino masses, see also Refs.^{7,8,9}.

2 Generation of neutrino masses by R-parity violation

To understand the effects of the bilinear and trilinear terms on neutrino mass matrices, let us consider them one by one. First, switch on only the bilinear δ_μ^i terms which appear in the superpotential. Such terms generate neutrino masses at the tree level which are proportional to $\delta_\mu^i \delta_\mu^j$. This constitutes a rank 1 mass matrix which leads to *only one* nonzero eigenvalue. This is not enough since we know that the solar and atmospheric neutrino data require at least two nonzero eigenvalues.

Then we turn on the bilinear δ_B^i terms which appear in the scalar potential. They contribute to neutrino mass at the loop level via the Grossman-Haber diagrams¹⁰, in which there are gauge couplings at the neutrino vertices while there are two types of $\mathcal{R}_p$ interactions giving rise to the $\Delta L = 2$ Majorana mass via the diagram of Fig. 1. The first type has $\mathcal{R}_p$ couplings located at positions III + IV (slepton-Higgs mixing) with contributions proportional to $\delta_B \delta_B$. In the second type, the $\mathcal{R}_p$ interactions are located at positions V + IV (neutrino-neutralino and slepton-Higgs mixing) with contributions proportional to $\delta_\mu \delta_B$. Now, the δ_μ^i and δ_B^i terms together give rise to two nonzero masses, while one eigenvalue still remains zero. As far as data is concerned, this scenario works¹¹.

Then we turn on the trilinear interaction for L violation, namely, the δ_λ^{ijk} (or $\delta_{\lambda'}^{ipq}$) couplings. We then have loops involving the trilinear $\mathcal{R}_p$ couplings λ or λ' at the neutrino vertices I and II in Fig. 1 (with lepton/slepton or quark/squark as propagators). They give contributions proportional to $\delta_\lambda \delta_\lambda$ (or $\delta_{\lambda'} \delta_{\lambda'}$). One also has the diagram of Fig. 2, where two units of L violation come from positions V (neutrino-neutralino mixing) and II (λ or λ' vertex). Their contribution to the neutrino mass is proportional to $\delta_\mu \delta_\lambda$ (or $\delta_\mu \delta_{\lambda'}$). Now, with bilinear and trilinear terms together, all the neutrinos become massive.

Figure 1: The usual loops ($\mathcal{R}_p$ at I + II) and the Grossman-Haber loops ($\mathcal{R}_p$ at III + IV or V + IV) contributing to the neutrino mass.

For the sake of simplicity, we set all unknown sparticle masses equal to $M_S = 100$ GeV. We then obtain a neutrino mass matrix of the form

$$[m_\nu]_{ij} = M_S \left[\delta_\mu^i \delta_\mu^j + \frac{\kappa_1}{\cos \beta} \left(\delta_\mu^i \delta_B^j + \delta_\mu^j \delta_B^i \right) + \frac{\kappa_1}{\cos^2 \beta} \delta_B^i \delta_B^j \right]$$

Figure 2: Loops with a gauge and a trilinear Yukawa coupling. The $\mathcal{H}_p$ interactions are located at V and II.

$$\begin{aligned}
& + \kappa_2 \left[\sum_{k,n} m_{e_n} m_{e_k} \delta_\lambda^{ink} \delta_\lambda^{jkn} + 3 \sum_{k,n} m_{d_n} m_{d_k} \delta_{\lambda'}^{ink} \delta_{\lambda'}^{jkn} \right] \\
& + \kappa_3 \left[\sum_k m_{e_k} (\delta_\mu^i \delta_\lambda^{jkk} + \delta_\mu^j \delta_\lambda^{ikk}) + 3 \sum_k m_{d_k} (\delta_\mu^i \delta_{\lambda'}^{jkk} + \delta_\mu^j \delta_{\lambda'}^{ikk}) \right],
\end{aligned} \tag{3}$$

where

$$\kappa_1 = \frac{g^2}{64\pi^2}, \quad \kappa_2 = \frac{1}{8\pi^2 M_S}, \quad \kappa_3 = \frac{g}{16\pi^2 \sqrt{2}}. \tag{4}$$

We have included for completeness the contributions arising from the $\delta_{\lambda'}$ terms which we set to zero in our numerical analysis. The simplest case to consider with a common $\delta_\mu^i \equiv \delta_\mu, \delta_B^i \equiv \delta_B$ and $\delta_\lambda^{ink} \equiv \delta_\lambda$ does not work as it cannot accomodate two large mixing angles for θ_{12} and θ_{23} .

In our numerical analysis we take : $\delta_\mu^i, \delta_B^i, \delta_\lambda^{ink} \equiv \delta_\lambda, \delta_{\lambda'}^{ink} = 0$, for $i = 1, 2, 3$, i.e., seven independent parameters. Note that a common δ_λ , in addition to δ_μ^i and δ_B^i terms, is enough to make all the neutrinos massive, and allows us to study how the presence of the trilinear interaction alters the allowed range of the bilinear parameters. Thus, the neutrino mass matrix elements will be given by,

$$\begin{aligned}
m_{11} &= M_S \left[(\delta_\mu^1)^2 + \frac{\kappa_1}{\cos^2 \beta} (\delta_B^1)^2 + 2 \frac{\kappa_1}{\cos \beta} \delta_\mu^1 \delta_B^1 \right] + 2\kappa_3 m_\tau \delta_\mu^1 \delta_\lambda + \kappa_2 m_\tau^2 \delta_\lambda^2, \\
m_{12} &= M_S \left[\delta_\mu^1 \delta_\mu^2 + \frac{\kappa_1}{\cos^2 \beta} \delta_B^1 \delta_B^2 + \frac{\kappa_1}{\cos \beta} (\delta_\mu^1 \delta_B^2 + \delta_\mu^2 \delta_B^1) \right] + \kappa_3 m_\tau (\delta_\mu^1 \delta_\lambda + \delta_\mu^2 \delta_\lambda) + \kappa_2 m_\tau^2 \delta_\lambda^2, \\
m_{22} &= M_S \left[(\delta_\mu^2)^2 + \frac{\kappa_1}{\cos^2 \beta} (\delta_B^2)^2 + 2 \frac{\kappa_1}{\cos \beta} \delta_\mu^2 \delta_B^2 \right] + 2\kappa_3 m_\tau \delta_\mu^2 \delta_\lambda + \kappa_2 m_\tau^2 \delta_\lambda^2, \\
m_{13} &= M_S \left[\delta_\mu^1 \delta_\mu^3 + \frac{\kappa_1}{\cos^2 \beta} \delta_B^1 \delta_B^3 + \frac{\kappa_1}{\cos \beta} (\delta_\mu^1 \delta_B^3 + \delta_\mu^3 \delta_B^1) \right] + \kappa_3 m_\tau \delta_\mu^3 \delta_\lambda, \\
m_{23} &= M_S \left[\delta_\mu^2 \delta_\mu^3 + \frac{\kappa_1}{\cos^2 \beta} \delta_B^2 \delta_B^3 + \frac{\kappa_1}{\cos \beta} (\delta_\mu^2 \delta_B^3 + \delta_\mu^3 \delta_B^2) \right] + \kappa_3 m_\tau \delta_\mu^3 \delta_\lambda, \\
m_{33} &= M_S \left[(\delta_\mu^3)^2 + \frac{\kappa_1}{\cos^2 \beta} (\delta_B^3)^2 + 2 \frac{\kappa_1}{\cos \beta} \delta_\mu^3 \delta_B^3 \right],
\end{aligned} \tag{5}$$

where we have employed the hierarchy of the charged fermion masses to keep only the dominant terms, i.e. those which involve m_τ .

3 Experimental data on neutrino masses and mixings

We write the PMNS matrix, which is the rotation matrix from neutrino flavour (f) to mass (i) eigenstates, as

$$V_{fi} = \begin{bmatrix} c_{12}c_{13} & c_{13}s_{12} & s_{13} \\ -c_{23}s_{12} - c_{12}s_{13}s_{23} & c_{12}c_{23} - s_{12}s_{13}s_{23} & c_{13}s_{23} \\ s_{23}s_{12} - c_{12}c_{23}s_{13} & -c_{12}s_{23} - c_{23}s_{12}s_{13} & c_{13}c_{23} \end{bmatrix}, \quad (6)$$

where $c_{ij} \equiv \cos \theta_{ij}$ and $s_{ij} \equiv \sin \theta_{ij}$. We have neglected the CP phases which are not relevant for our purpose of extracting allowed ranges of new physics from oscillation analysis. We take the solar anomaly to be a consequence of ν_e - ν_μ oscillation, and the relevant mass squared difference is $\Delta m_{12}^2 = \Delta m_{\text{solar}}^2$. We consider the atmospheric oscillation to be between ν_μ and ν_τ , and the relevant mass squared difference is $\Delta m_{13}^2 \approx \Delta m_{23}^2 = \Delta m_{\text{atm}}^2$. After the announcement of the SNO data, the MSW-LMA oscillation is the most favoured solution with $\Delta m_{\text{solar}}^2 = (2.5 - 19.0) \times 10^{-5} \text{ eV}^2$ and $\sin^2 2\theta_{12} = 0.61 - 0.95$. The SuperK atmospheric neutrino data suggest $\Delta m_{\text{atm}}^2 = (2 - 5) \times 10^{-3} \text{ eV}^2$ with $\sin^2 2\theta_{23} = 0.88 - 1.0$. The Chooz and Palo Verde long baseline reactor experiments constrain $\sin^2 \theta_{13} \lesssim 0.04$. Tritium β -decay requires that the absolute mass is $m_{\nu_e} \lesssim 2.2 \text{ eV}$. For the references of all the experimental data, see⁶.

4 Results and conclusions

- We have performed a general scan of parameter space made up by the seven parameters (three δ_μ^i , three δ_B^i , one δ_λ) that appear in the mass matrix. We allow the tree-level contributions to either dominate over the loop corrections, to be on the same order as these, or to be much smaller than the loop terms. The fitted values of the couplings, satisfying all the data mentioned in the previous section, are given in table I.
- In Fig. 3 we have presented the allowed region in the $|\delta_B| = \sqrt{\sum_i (\delta_B^i)^2}$ versus $|\delta_\mu| = \sqrt{\sum_i (\delta_\mu^i)^2}$ plane for the combined fit. We show our results for both $\delta_\lambda \neq 0$ and $\delta_\lambda = 0$. It can be seen that the allowed region increases when we admit non-zero values of δ_λ . This happens due to the presence of the $\delta_\mu \delta_\lambda$ terms in the mass matrix (originating from Fig. 2) which can take either sign thus accomodating a larger region of the parameter space. This figure should be compared with Fig. 5 of Ref. ¹¹.
- The resulting fit strongly prefers a hierarchical mass pattern in our scenario, although a distinction between the inverted and the normal hierarchy is not possible.
- The maximum value of m_{eff} we have predicted (see Table 1) can hopefully be tested in the next generation of neutrinoless double beta decay experiments. The range again implies that the spectrum is not degenerate¹².
- Allowing a non-vanishing δ_λ will not qualitatively change the pattern of our fit.
- The analysis was done before the first announcement of the KamLAND results. The pattern of the fit will not be qualitatively altered if we include the KamLAND data.

Acknowledgments

I (G.B.) thank the organizers of the Moriond Conference for the invitation to give this talk, for partial financial assistance, as well as for the warm hospitality they provided in such a beautiful ambiance in the French Alps!
